Here is an inline example, \$ \pi(\theta) \$,

an equation,

$$abla f(x) \in \mathbb{R}^n,$$

and a regular \$ symbol.

Define \$f(x)\$:

Traceback (most recent call last):
 File "<stdin>", line 1, in <module>
TypeError: floats_only(): incompatible function arguments. The following argument types are supported:
 1. (f: float) -> float
Invoked with: 4
```

000000000 \_a 0000000000000000 py::arg().noconvert() 0

#### 7.9 00/00000

```
py::class_<Dog>(m, "Dog").def(py::init<>());
py::class_<Cat>(m, "Cat").def(py::init<>());
m.def("bark", [](Dog *dog) -> std::string {
 if (dog) return "woof!"; /* Called with a Dog instance */
 else return "(no dog)"; /* Called with None, dog == nullptr */
}, py::arg("dog").none(true));
m.def("meow", [](Cat *cat) -> std::string {
 // Can't be called with None argument
 return "meow";
}, py::arg("cat").none(false));
```

## DDDPythonDD bark(None) DDD "(no dog)" DDD meow(None) DDDDD TypeError D

#### 

Note: Even when <code>.none(true)</code> is specified for an argument, <code>None</code> will be converted to a <code>nullptr only</code> for custom and opaque types. Pointers to built-in types (<code>double \*, int \*, ...)</code> and STL types (<code>std::vector<T> \*, ...;</code> if <code>pybind11/stl.h</code> is included) are copied when converted to C++ (see Overview) and will not allow <code>None</code> as argument. To pass optional argument of these copied types consider using <code>std::optional<T></code>

```

#### Note∏

- because in these cases there is no C++ variable to reference (the value is stored in the referenced Python variable), pybind11 provides one in the PYBIND11\_OVERRIDE macros (when needed) with static storage duration. Note that this means that invoking the overridden method on *any* instance will change the referenced value stored in *all* instances of that type.
- Attempts to modify a non-const reference will not have the desired effect: it will change only the static cache variable, but this change will not propagate to underlying Python instance, and the change will be replaced the next time the override is invoked.

# 8.10 □□pickle

```
class Pickleable {
public:
 Pickleable(const std::string &value) : m_value(value) { }
 const std::string &value() const { return m_value; }

 void setExtra(int extra) { m_extra = extra; }
 int extra() const { return m_extra; }

private:
 std::string m_value;
 int m_extra = 0;
};
```

```
try:
 import cPickle as pickle # Use cPickle on Python 2.7
except ImportError:
 import pickle

p = Pickleable("test_value")
p.setExtra(15)
data = pickle.dumps(p, 2)
```

Note: Note that only the cPickle module is supported on Python 2.7.

The second argument to <code>dumps</code> is also crucial: it selects the pickle protocol version 2, since the older version 1 is not supported. Newer versions are also fine—for instance, specify <code>-1</code> to always use the latest available version. Beware: failure to follow these instructions will cause important pybind11 memory allocation routines to be skipped during unpickling, which will likely lead to memory corruption and/or segmentation faults.

 ('Fluffy', 'Rover')
>>> (cats.pet_name(mydog), dogs.pet_name(mycat), frogs.pet_name(mycat))
 ('Rover', 'Fluffy', 'Fluffy')
```

Note: STL bindings (as provided via the optional pybind11/stl\_bind.h header) apply py::module\_local by default when the bound type might conflict with other modules; see Binding STL containers for details.

The localization of the bound types is actually tied to the shared object or binary generated by the compiler/linker. For typical modules created with PYBIND11\_MODULE(), this distinction is not significant. It is possible, however, when Embedding the interpreter to embed multiple modules in the same binary (see Adding embedded modules). In such a case, the localization will apply across all embedded modules within the same binary.

TypeError: type 'IsFinal' is not an acceptable base type
```

# 8.16

pybind11::polymorphic\_type\_hook template:

```
enum class PetKind { Cat, Dog, Zebra };
struct Pet { // Not polymorphic: has no virtual methods
 const PetKind kind;
 int age = 0;
 protected:
 Pet(PetKind _kind) : kind(_kind) {}
struct Dog : Pet {
 Dog() : Pet(PetKind::Dog) {}
 std::string sound = "woof!";
 std::string bark() const { return sound; }
};
namespace pybind11 {
 template<> struct polymorphic_type_hook<Pet> {
 static const void *get(const Pet *src, const std::type_info*& type) {
 if (src && src->kind == PetKind::Dog) {
 type = &typeid(Dog);
 return static_cast<const Dog*>(src);
 return src;
 };
```

When pybind11 wants to convert a C++ pointer of type Base\* to a Python object, it calls polymorphic\_type\_hook<Base>::get() to determine if a downcast is possible. The get() function should use whatever runtime information is available to determine if its src parameter is in fact an instance of some class Derived that inherits from Base. If it finds such a Derived, it sets type = &typeid(Derived) and returns a pointer to the Derived object that contains src. Otherwise, it just returns src, leaving type at its default value of nullptr. If you set type to a type that pybind11 doesn't know about, no downcasting will occur, and the original src pointer will be used with its static type Base\*.

It is critical that the returned pointer and type argument of get() agree with each other: if type is set to something non-null, the returned pointer must point to the start of an object whose type is type. If the hierarchy being exposed uses only single inheritance, a simple return src; will achieve this just fine, but in the general case, you must cast src to the appropriate derived-class pointer (e.g. using static\_cast<Derived>(src)) before allowing it to be returned as a void\*.

py::register_local_exception<CppExp>(module, "PyExp", PyExc_RuntimeError);
```

000PyExp000000PyExp0RuntimeError0

Inside the translator, std::rethrow\_exception should be used within a try block to re-throw the exception. One or more catch clauses to catch the appropriate exceptions should then be used with each clause using PyErr\_SetString to set a Python exception or ex(string) to set the python exception to a custom exception type (see below).

To declare a custom Python exception type, declare a py::exception variable and use this in the associated exception translator (note: it is often useful to make this a static declaration when using it inside a lambda expression without requiring capturing).

The following example demonstrates this for a hypothetical exception classes MyCustomException and OtherException: the first is translated to a custom python exception MyCustomError, while the second is translated to a standard python RuntimeError:

```
static py::exception<MyCustomException> exc(m, "MyCustomError");
py::register_exception_translator([](std::exception_ptr p) {
 try {
 if (p) std::rethrow_exception(p);
 } catch (const MyCustomException &e) {
 exc(e.what());
 } catch (const OtherException &e) {
 PyErr_SetString(PyExc_RuntimeError, e.what());
 }
});
```

Multiple exceptions can be handled by a single translator, as shown in the example above. If the exception is not caught by the current translator, the previously registered one gets a chance.

If none of the registered exception translators is able to handle the exception, it is handled by the default converter as described in the previous section.

# 9.3 Local vs Global Exception Translators

When a global exception translator is registered, it will be applied across all modules in the reverse order of registration. This can create behavior where the order of module import influences how exceptions are translated.

If module1 has the following translator:

```
py::register_exception_translator([](std::exception_ptr p) {
 try {
 if (p) std::rethrow_exception(p);
 } catch (const std::invalid_argument &e) {
 PyErr_SetString("module1 handled this")
 }
}
```

and module2 has the following similar translator:

```
py::register_exception_translator([](std::exception_ptr p) {
 try {
 if (p) std::rethrow_exception(p);
 } catch (const std::invalid_argument &e) {
 PyErr_SetString("module2 handled this")
 }
}
```

then which translator handles the invalid\_argument will be determined by the order that module1 and module2 are imported. Since exception translators are applied in the reverse order of registration, which ever module was imported last will "win" and that translator will be applied.

If there are multiple pybind11 modules that share exception types (either standard built-in or custom) loaded into a single python instance and consistent error handling behavior is needed, then local translators should be used.

Changing the previous example to use register\_local\_exception\_translator would mean that
when invalid\_argument is thrown in the module2 code, the module2 translator will always handle it,
while in module1, the module1 translator will do the same.

#### 11.2.4 0000

```
m.def("pass_char", [](char c) { return c; });
m.def("pass_wchar", [](wchar_t w) { return w; });

example.pass_char("A")
'A'
```

```
>>> example.pass_char(0x65)
TypeError
>>> example.pass_char(chr(0x65))
'A'
```

000008-bit00000 int8\_t 0 uint8\_t 000000

# 11.2.5 Grapheme clusters

A single grapheme may be represented by two or more Unicode characters. For example 'é' is usually represented as U+00E9 but can also be expressed as the combining character sequence U+0065 U+0301 (that is, the letter 'e' followed by a combining acute accent). The combining character will be lost if the two-character sequence is passed as an argument, even though it renders as a single grapheme.

```
>>> example.pass_wchar("é")
'é'
>>> combining_e_acute = "e" + "\u0301"
>>> combining_e_acute
'é'
>>> combining_e_acute == "é"
False
>>> example.pass_wchar(combining_e_acute)
'e'
```

Normalizing combining characters before passing the character literal to C++ may resolve *some* of these issues:

```
>>> example.pass_wchar(unicodedata.normalize("NFC", combining_e_acute))
'é'
```

In some languages (Thai for example), there are graphemes that cannot be expressed as a single Unicode code point, so there is no way to capture them in a C++ character type.

# 11.2.6 c++17 string\_view

C++17 string views are automatically supported when compiling in C++17 mode. They follow the same rules for encoding and decoding as the corresponding STL string type (for example, a std::u16string\_view argument will be passed UTF-16-encoded data, and a returned std::string\_view will be decoded as UTF-8).

## 11.3 STL [] []

#### 11.3.1

#### 11.3.2 C++17000

```
// `boost::optional` as an example -- can be any `std::optional`-like container
namespace pybind11 { namespace detail {
 template <typename T>
 struct type_caster<boost::optional<T>> : optional_caster<boost::optional<T>> {};
}}
```

The visit\_helper specialization is not required if your name::variant provides a name::visit() function. For any other function name, the specialization must be included to tell pybind11 how to visit the variant.

Warning: When converting a variant type, pybind11 follows the same rules as when determining which function overload to call (Overload resolution order), and so the same caveats hold. In particular, the order in which the variant's alternatives are listed is important, since pybind11 will try conversions in this order. This means that, for example, when converting variant<int, bool>, the bool variant will never be selected, as any Python bool is already an int and is convertible to a C++ int. Changing the order of alternatives (and using variant<bool, int>, in this example) provides a solution.

# **11.3.3** □□opaque□□

```
void append_1(std::vector<int> &v) {
 v.push_back(1);
}
```

#### □Python

```
>>> v = [5, 6]

- std::chrono::[other\_clocks]::time\_point → datetime.timedelta

#### Python C++

```
 datetime.datetime Or datetime.time →
 std::chrono::system_clock::time_point
 datetime.timedelta → std::chrono::duration
 datetime.timedelta → std::chrono::[other_clocks]::time_point
 float → std::chrono::duration
 float → std::chrono::[other_clocks]::time_point
```

# 11.6 Eigen

0000Eigen000000

#### **11.7** 0000000

The following snippets demonstrate how this works for a very simple inty type that that should be convertible from Python types that provide a \_\_int\_\_(self) method.

```
struct inty { long long_value; };

void print(inty s) {
 std::cout << s.long_value << std::endl;
}</pre>
```

The following Python snippet demonstrates the intended usage from the Python side:

```
class A:
 def __int__(self):
 return 123

from example import print
print(A())
```

To register the necessary conversion routines, it is necessary to add an instantiation of the pybind11::detail::type\_caster<T> template. Although this is an implementation detail, adding an instantiation of this type is explicitly allowed.

```
namespace pybind11 { namespace detail {
 template <> struct type_caster<inty> {
 public:
 PYBIND11_TYPE_CASTER(inty, _("inty"));
 bool load(handle src, bool) {
 PyObject *source = src.ptr();
 PyObject *tmp = PyNumber_Long(source);
 if (!tmp)
 return false;
 value.long_value = PyLong_AsLong(tmp);
 Py_DECREF(tmp);
 return !(value.long_value == -1 && !PyErr_Occurred());
 static handle cast(inty src, return_value_policy /* policy */, handle /* parent */)
 return PyLong_FromLong(src.long_value);
 };
}} // namespace pybind11::detail
```

Warning: When using custom type casters, it's important to declare them consistently in every compilation unit of the Python extension module. Otherwise, undefined behavior can ensue.

# **12. Python C++**□□

pybind110000C++0000Python00000000000000C++000Python00000Python C API0

# **12.1 Python** □ □

#### **12.1.1** 00000

Warning: Be sure to review the Gotchas before using this heavily in your C++ API.

# **12.1.2 C++00000Python00**

00000000 dict 00000000

```
using namespace pybind11::literals; // to bring in the `_a` literal py::dict d("spam"_a=py::none(), "eggs"_a=42);

tuple000000 py::make_tuple() 0000
```

```
py::tuple tup = py::make_tuple(42, py::none(), "spam");
```

0000000000000Python000

simple namespace

```
using namespace pybind11::literals; // to bring in the `_a` literal
py::object SimpleNamespace = py::module_::import("types").attr("SimpleNamespace");
py::object ns = SimpleNamespace("spam"_a=py::none(), "eggs"_a=42);
```

namespace0000000 py::delattr() 0 py::getattr() 0 py::setattr() 0000Simple namespaces0000

#### 12.1.3

00000000000C++00000Python000000py::cast() 0000

MyClass \*cls = obj.cast<MyClass \*>();

#### 12.1.4 **C++DPython**

```
// Equivalent to "from decimal import Decimal"
py::object Decimal = py::module_::import("decimal").attr("Decimal");

// Try to import scipy
py::object scipy = py::module_::import("scipy");
return scipy.attr("__version__");
```

## **12.1.5 D Python D**

Operator() OOOOPythonOOOOOO

```
// Construct a Python object of class Decimal
py::object pi = Decimal("3.14159");

// Use Python to make our directories
py::object os = py::module_::import("os");
py::object makedirs = os.attr("makedirs");
makedirs("/tmp/path/to/somewhere");
```

One can convert the result obtained from Python to a pure C++ version if a py::class\_ or type conversion is defined.

```
py::function f = <...>;
py::object result_py = f(1234, "hello", some_instance);
MyClass &result = result_py.cast<MyClass>();
```

# **12.1.6 DPython DD**

00 .attr 000000Python000

```
// Calculate eⁿπ in decimal
py::object exp_pi = pi.attr("exp")();
py::print(py::str(exp_pi));
```

In the example above pi.attr("exp") is a bound method: it will always call the method for that same instance of the class. Alternately one can create an unbound method via the Python class (instead of instance) and pass the self object explicitly, followed by other arguments.

```
py::object decimal_exp = Decimal.attr("exp");

// Compute the e^n for n=0..4
for (int n = 0; n < 5; n++) {
 py::print(decimal_exp(Decimal(n));
}</pre>
```

#### **12.1.7** 00000

#### 00000000Python000000

```
def f(number, say, to):
 ... # function code

f(1234, say="hello", to=some_instance) # keyword call in Python
```

#### C++00000000

```
using namespace pybind11::literals; // to bring in the `_a` literal
f(1234, "say"_a="hello", "to"_a=some_instance); // keyword call in C++
```

#### 12.1.8 0000

#### 0000 \*args 0 \*\*kwargs 00000000000

```
// * unpacking
py::tuple args = py::make_tuple(1234, "hello", some_instance);
f(*args);

// ** unpacking
py::dict kwargs = py::dict("number"_a=1234, "say"_a="hello", "to"_a=some_instance);
f(**kwargs);

// mixed keywords, * and ** unpacking
py::tuple args = py::make_tuple(1234);
py::dict kwargs = py::dict("to"_a=some_instance);
f(*args, "say"_a="hello", **kwargs);
```

Generalized unpacking according to PEP448 is also supported:

```
py::dict kwargs1 = py::dict("number"_a=1234);
py::dict kwargs2 = py::dict("to"_a=some_instance);
f(**kwargs1, "say"_a="hello", **kwargs2);
```

#### 12.1.9

```
#include <pybind11/numpy.h>
using namespace pybind11::literals;

py::module_ os = py::module_::import("os");
py::module_ path = py::module_::import("os.path"); // like 'import os.path as path'
py::module_ np = py::module_::import("numpy"); // like 'import numpy as np'

py::str curdir_abs = path.attr("abspath")(path.attr("curdir"));
py::print(py::str("Current directory: ") + curdir_abs);
py::dict environ = os.attr("environ");
py::print(environ["HOME"]);
py::array_t<float> arr = np.attr("ones")(3, "dtype"_a="float32");
py::print(py::repr(arr + py::int_(1)));
```

#### Note

If a trivial conversion via move constructor is not possible, both implicit and explicit casting (calling obj.cast()) will attempt a "rich" conversion. For instance, py::list env = os.attr("environ"); will succeed and is equivalent to the Python code env = list(os.environ) that produces a list of the dict keys.

#### 12.1.10

#### 12.1.11 Gotchas

 ptr3[idx] = ptr1[idx] + ptr2[idx];
 return result;
PYBIND11_MODULE(test, m) {
 m.def("add_arrays", &add_arrays, "Add two NumPy arrays");
```

#### 12.2.5

The returned proxy object supports some of the same methods as py::array so that it can be used as a drop-in replacement for some existing, index-checked uses of py::array:

- .ndim() returns the number of dimensions
- .data(1, 2, ...) and r.mutable\_data(1, 2, ...) returns a pointer to the const T or T data, respectively, at the given indices. The latter is only available to proxies obtained via a.mutable\_unchecked().
- .itemsize() returns the size of an item in bytes, i.e. sizeof(T).
- .ndim() returns the number of dimensions.
- .shape(n) returns the size of dimension n
- .size() returns the total number of elements (i.e. the product of the shapes).
- .nbytes() returns the number of bytes used by the referenced elements (i.e. itemsize() times size()).

#### 12.2.6

Python 3 provides a convenient ... ellipsis notation that is often used to slice multidimensional arrays. For instance, the following snippet extracts the middle dimensions of a tensor with the first and last index set to zero. In Python 2, the syntactic sugar ... is not available, but the singleton Ellipsis (of type ellipsis) can still be used directly.

```
a = ... # a NumPy array
b = a[0, ..., 0]
```

The function py::ellipsis() function can be used to perform the same operation on the C++ side:

```
py::array a = /* A NumPy array */;
py::array b = a[py::make_tuple(0, py::ellipsis(), 0)];
```

#### **12.2.7 0000**

Note: memoryview::from\_memory is not available in Python 2.

#### **12.3** ПППП

#### **12.3.1 C++DDPython print**

DDDDDPython print DDD sep, end, file, flush DDDD

#### **12.3.2 Oostream**

#### Warning

The redirection can also be done in Python with the addition of a context manager, using the py::add\_ostream\_redirect() <add\_ostream\_redirect> function:

```
py::add_ostream_redirect(m, "ostream_redirect");
```

The name in Python defaults to ostream\_redirect if no name is passed. This creates the following context manager in Python:

```
with ostream_redirect(stdout=True, stderr=True):
 noisy_function()
```

It defaults to redirecting both streams, though you can use the keyword arguments to disable one of the streams if needed.

#### **12.3.3 00000000Python00**

pybind11 provides the eval, exec and eval\_file functions to evaluate Python expressions and statements. The following example illustrates how they can be used.

```
// At beginning of file
#include <pybind11/eval.h>
...

// Evaluate in scope of main module
py::object scope = py::module_::import("__main__").attr("__dict__");

// Evaluate an isolated expression
int result = py::eval("my_variable + 10", scope).cast<int>();

// Evaluate a sequence of statements
py::exec(
 "print('Hello')\n"
 "print('world!');",
 scope);

// Evaluate the statements in an separate Python file on disk
py::eval_file("script.py", scope);
```

C++11 raw string literals are also supported and quite handy for this purpose. The only requirement is that the first statement must be on a new line following the raw string delimiter R" (, ensuring all lines have common leading indent:

```
py::exec(R"(
 x = get_answer()
 if x == 42:
 print('Hello World!')
 else:
 print('Bye!')
)", scope
);
```

## **13.** 00000

#### 13.1 0000

```
cmake_minimum_required(VERSION 3.4)
project(example)

find_package(pybind11 REQUIRED) # or `add_subdirectory(pybind11)`

add_executable(example main.cpp)
target_link_libraries(example PRIVATE pybind11::embed)
```

#### main.cpp 0000000

```
#include <pybind11/embed.h> // everything needed for embedding
namespace py = pybind11;
int main() {
 py::scoped_interpreter guard{}; // start the interpreter and keep it alive
 py::print("Hello, World!"); // use the Python API
}
```

## **13.2 DPython**

### 00000pybind11 API0000000000012000

```
#include <pybind11/embed.h>
namespace py = pybind11;
using namespace py::literals;

int main() {
 py::scoped_interpreter guard{};

 auto kwargs = py::dict("name"_a="World", "number"_a=42);
 auto message = "Hello, {name}! The answer is {number}"_s.format(**kwargs);
 py::print(message);
}
```

#### 00000000000000

#### 12.3

#### DD module\_::import() DDDDPythonDDD

```
py::module_ sys = py::module_::import("sys");
py::print(sys.attr("path"));
```

```
"""calc.py located in the working directory"""

def add(i, j):
 return i + j
```

```
py::module_ calc = py::module_::import("calc");
py::object result = calc.attr("add")(1, 2);
int n = result.cast<int>();
assert(n == 3);
```

#### **12.4** 000000

```
#include <pybind11/embed.h>
namespace py = pybind11;

PYBIND11_EMBEDDED_MODULE(fast_calc, m) {
 // `m` is a `py::module_` which is used to bind functions and classes
 m.def("add", [](int i, int j) {
 return i + j;
 });
}

int main() {
 py::scoped_interpreter guard{};

 auto fast_calc = py::module_::import("fast_calc");
 auto result = fast_calc.attr("add")(1, 2).cast<int>();
 assert(result == 3);
}
```

Unlike extension modules where only a single binary module can be created, on the embedded side an unlimited number of modules can be added using multiple PYBIND11\_EMBEDDED\_MODULE definitions (as long as they have unique names).

These modules are added to Python's list of builtins, so they can also be imported in pure Python files loaded by the interpreter. Everything interacts naturally:

```
"""py_module.py located in the working directory"""
import cpp_module
a = cpp_module.a
b = a + 1
#include <pybind11/embed.h>
namespace py = pybind11;
PYBIND11_EMBEDDED_MODULE(cpp_module, m) {
 m.attr("a") = 1;
int main() {
 py::scoped_interpreter guard{};
 auto py_module = py::module_::import("py_module");
 auto locals = py::dict("fmt"_a="{} + {} = {}", **py_module.attr("__dict__"));
 assert(locals["a"].cast<int>() == 1);
 assert(locals["b"].cast<int>() == 2);
 py::exec(R"(
 c = a + b
 message = fmt.format(a, b, c)
)", py::globals(), locals);
 assert(locals["c"].cast<int>() == 3);
 assert(locals["message"].cast<std::string>() == "1 + 2 = 3");
```

#### **12.5** 00000000

#### Warning

Creating two concurrent scoped\_interpreter guards is a fatal error. So is calling initialize\_interpreter for a second time after the interpreter has already been initialized.

Do not use the raw CPython API functions Py\_Initialize and Py\_Finalize as these do not properly handle the lifetime of pybind11's internal data.

Reference

The following admonishments are implemented by the mdbook-admonish plugin and are automatically themed to match Catppuccin.

Directives

All supported directives are listed below.

note

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

abstract, summary, tldr

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

info, todo

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

tip, hint, important

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

success, check, done

Success

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

question, help, faq

Question

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

warning, caution, attention

Warning

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

failure, fail, missing

X Failure

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

danger, error

Danger

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

bug

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

example

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

quote, cite

77 Quote

Rust is a multi-paradigm, general-purpose programming language designed for performance and safety, especially safe concurrency.

Bienvenue sur notre site de développement 3D

Bienvenue sur notre site dédié au développement 3D. lci, vous trouverez des ressources, des tutoriels et des informations utiles pour vous lancer dans le monde passionnant de la 3D.

1 Info

A beautifully styled message.

i≡ Un example

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla et euismod nulla. Curabitur feugiat, tortor non consequat finibus, justo purus auctor massa, nec semper lorem quam in massa.

Une note

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla et euismod nulla. Curabitur feugiat, tortor non consequat finibus, justo purus auctor massa, nec semper lorem quam in massa.

▲ Un warning

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla et euismod nulla. Curabitur feugiat, tortor non consequat finibus, justo purus auctor massa, nec semper lorem quam in massa.

Collapsing note

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla et euismod nulla. Curabitur feugiat, tortor non consequat finibus, justo purus auctor massa, nec semper lorem quam in massa.

♦ Le javascript c'est yolo préférez Typescript

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla et euismod nulla. Curabitur feugiat, tortor non consequat finibus, justo purus auctor massa, nec semper lorem quam in massa.

6 Referencing and dereferencing

The opposite of *referencing* by using & is *dereferencing*, which is accomplished with the dereference operator, *.

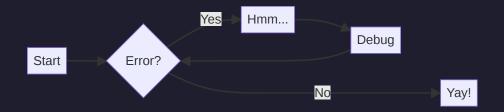

Bug

This syntax won't work in Python 3:

print "Hello, world!"

À propos de nous

Nous sommes une équipe passionnée par la 3D et nous avons pour mission de partager nos connaissances avec la communauté. Vous trouverez ici des articles, des exemples de code et des démonstrations pour vous aider à démarrer votre voyage dans le développement 3D.

Pour commencer

Si vous êtes nouveau dans le domaine de la 3D, ne vous inquiétez pas ! Notre page "Getting Started" vous guidera à travers les étapes essentielles pour démarrer rapidement.

Restons en contact

N'hésitez pas à nous suivre sur les réseaux sociaux pour rester à jour avec nos dernières publications et annonces. Si vous avez des questions ou des commentaires, n'hésitez pas à nous contacter!

Here is an inline example, \$ \pi(\theta) \$,

an equation,

$$abla f(x) \in \mathbb{R}^n,$$

and a regular \$ symbol.

Define \$f(x)\$:

$$f(x)=x^2 \ x \in ackslash {f R}$$
